Introduction

Berry and Burch (1978), Burch (1979), and Parrack (1993a,b) described the fishery background and biological information for the U.S. Atlantic greater amberjack, *Seriola dumerili* fisheries through 1992. These reports documented commercial and recreational amberjack fisheries of the western central Atlantic area, noted the explosive increases of commercial landings off south Florida during the middle 1980's, and documented the lack of recorded information on the quantity of catch. Amberjacks, as food, were believed wasted or underutilized in many areas until the mid 1970's however, as the recognition of amberjack as a prized gamefish and the popularity of smoked amberjack grew among fishermen utilization of this species was enhanced. Recreational fishing for amberjacks from New York to Texas was known to have occurred at least since the early 1950s but mostly incidental to other species; amberjacks were not a target species until the 1970's. Amberjacks began to be targeted by private boat fishermen, who enjoyed spear fishing and jig fishing from wrecks, and by many charter boat for hire operators because of their aggressive fighting behavior when hooked (Berry and Burch 1978). According to early researchers charterboat vessels landed the majority of amberjack in many areas and headboat vessels traditionally landed less catch than either charterboat or private angler vessels.

Increasing amberjack catches during the late 1970's and increased food utilization of amberjacks prompted researchers to begin collection of fisheries statistics and biological samples. Berry and Burch provided landings data for the amberjack fisheries in Dade County, Florida and average annual size data for one year from charter vessel landings based on a report by Gentle (1977). Accurate reporting of catches continues to be hampered to this day by problems associated with proper identification in the field by recreational and commercial anglers, seafood buyers, and even among scientists for small fish. The historical commercial and recreational landings are thought to have been underestimated prior to the 1980's (Berry and Burch 1978). In fact, Berry and Burch estimated that the 1975 amberjack landings in the U.S., alone were 2.5 times, that reported by the Food and Agriculture Organization (FAO) Yearbook of Fishery Statistics for the entire western central Atlantic. Berry and Burch (1978) further noted that many recreational fishermen operators of rental vessels sold part or all of their amberjack catches, making it more difficult to accurately quantify historical catch levels. Hartig (1991) noted that under-reporting of commercial landings on the Florida East coast may have continued through the mid to late 1990's.

Parrack (1993a,b), Cummings and McClellan (1996, 1997), Potts et al. (1998), Cummings (1998) and Potts and Burton (1999) gave some information regarding the status of the Atlantic greater amberjack stock. Cummings and McClellan (1996) used Virtual Population Analysis (VPA) to estimate stock size levels, fishing mortality rates, and provided preliminary information on spawning stock biomass per recruit (SSR). Potts et al. (1998) and Potts and Burton (1999) gave an account of the fishery through 1996. Neither the Potts et al (1998) nor the Potts and Burton (1999) study is directly comparable with the Parrack (1993a,b), or the Cummings and McClellan (1996, 1997), or the Cummings (1998) study since the headboat fishery catch data for 1981 - 1985 was

not the same. Potts et al. (1998) estimated the headboat catch for 1981-1985 from their database whereas Cummings and McClellan (1996) used the combined charter/headboat catch estimates from the MRFSS survey. Therefore, the results of their analyses are not exactly comparable. The recent study that evaluated the stock status, Cummings and McClellan (1996, 1997), identified problems in the data regarding catch and landings data, available samples, and subsequent VPA analyses which reduced the overall confidence in the results and in providing reliable management advice. Future projections were not done because the confidence in the VPA results was low.

In this report the U.S. fishery commercial, recreational charter, private, shore, and headboat fishery statistics are updated for the Atlantic greater amberjack stock. The recent interim report for this stock presented data through the 1997 calendar year (Cummings 1998). Additional regulatory changes have occurred since the first stock evaluation and three more years of data are available to use in re-evaluating stock status exist. Amendment #9 to the Fishery Management Plan for the Snapper-Grouper Fishery (Amend. #9, SG-FMP enacted February 24 1999) 1) reduced the recreational bag limit from 3 to 1 fish per person per day; 2) restricted harvest and possession in excess of the bag limit during April in the federal EEZ; 3) prohibits sale of fish caught under the bag limit when the commercial fishery is closed; 4) set the fishing year as May 1 through April 30; 5) prohibited coring; and 6) established a commercial quota, retroactive to 1998, of 1,169,931 pounds (gutted weight) based on 63% of the 1995 landings.

Atlantic greater amberjack commercial landings, recreational and headboat catches, and observed size frequency samples are summarized through the 1998 calendar year and information is also summarized on a fishing year basis (i.e., May 1-April 30) through the 1997 fishing year. Because fishery managers will be making a transition from calendar year to fishing year management for this stock, selected summary information is provided in this report using in both calendar year and fishing year format. Information on recreational releases, not previously included in earlier reports is provided. Revised estimates of the catch at size and catch at age for the commercial, recreational, and headboat fisheries are presented that incorporate three additional years of data obtained since the Cummings and McClellan (1996) assessment. Catch at size estimation incorporated improvements in the procedures used to allocate catch samples to catches. The information presented herein provided the statistical database for subsequent analyses of the stock condition.

Materials and Methods

Commercial Landings and Recreational Catches

The sources of data for this study were identical to those of Parrack (1993a), Cummings and McClellan (1996, 1997), and Cummings (1998) and were described in detail in the 1993 and 1996 reports. Reported commercial landings are updated through December 1998, estimates of the recreational harvest catch (A+B1) and released catch (B2) from the Marine Recreational Fisheries Statistics Survey (MRFSS) survey were replaced in total from 1981 through 1998. Estimates of catch from the headboat fishery were replaced in

total using the NMFS Beaufort Laboratory Headboat Survey database, as in previous reports and these data were available through December 1997. Fishing year 1997 was incomplete for the headboat fishery catch database, as the last four months catch (January – April 1998) were not available. The headboat fishery catch (in numbers of fish) for January through April of 1998 was estimated by substituting the quantity of catch reported for January – April 1997. Where necessary, commercial landings were converted from gutted to whole weight units using the NMFS conversion factor of 1.04 (Guy Davenport pers. comm.).

Commercial landings data and recreational catches were apportioned into Gulf Vs Atlantic stock units using the rationale prescribed in Parrack (1993a, b), continued in Cummings and McClellan (1996) and Cummings (1998). An important change in the Florida statistical landings occurred since the 1996 analysis. Previously, Florida's commercial landings data as obtained through the National Marine Fisheries Service (NMFS) General Canvas Landings Reporting System (GCLRS), existed in two format types: 1) since 1962 one landing record per year, month, dealer, and county of landing or 2) since about 1977 one landing record per year, dealer, gear and NMFS Statistical Shrimp Grid (proxy for area of capture). For this study and in Cummings (1998) the 1997 and 1998 Florida landings General Canvas data contained all of these attributes recorded on each record (year, month, county landed, dealer, gear, and NMFS area of capture). The effect of this change in the Florida commercial data is that the area and gear of capture are no longer assigned by NMFS port agents to the monthly landings data because gear and area information is recorded on the at the trip level for all finfish landed in Florida. The additional information should improve the area caught and gear resolution in basic data.

As in the previous Cummings and McClellan (1996) and Cummings (1998) reports, estimates of recreational catch of Atlantic greater amberjack from the MRFSS survey represent revised estimates as of May 1995, with the new estimates extended back in time to 1981. The catch estimates for 1979 and 1980 were not re-estimated by MRFSS and although 1979 and 1980 calendar years were included in the earlier Parrack (1993a,b) analyses, these years were excluded from the Cummings and McClellan (1996, 1997) and by Cummings (1998) analyses to maintain consistency in the estimates and are also excluded in this report and in subsequent analyses of the stock condition.

Estimation of Total Recreational and Commercial Catch at Size and At Age

The Atlantic greater amberjack stock length frequency sample database used by Cummings and McClellan (1996, 1997) was replaced completely. The distribution of the individual samples was considered with respect to temporal (year and month) and spatial (state and county) coverage for each of the main amberjack fisheries. The individual samples were pooled within specific fisheries (commercial handline, commercial dive, commercial bottom longline, commercial other (trap, fish trawl, seine), recreational (charter, private, shore), and headboat and the annual yearly length density was matched to the corresponding catch (recreational estimate) or to a yield (commercial). Where a sufficient number of observations ($n > 100$) existed and the length frequency distribution did not appear skewed, samples were matched at the year, state, and gear level. Lack of

sufficient samples at the monthly level precluded including month as a stratification level into the assignment of catch samples for any fishery. For each commercial landing, the sample average weight was divided into the reported yield in pounds to give an estimate of total catch in numbers. The estimated total numbers caught was apportioned over length according to the pooled length frequency sample. Weight length equation parameters were those developed by Burch (1979) for the Atlantic Ocean greater amberjack (W (lbs.) = $6.40 * 10^{-5} * \text{fork length (mm)}^{2.842}$; $n = 191$ fish in the sample ranging in size from 350 mm to 1,400 mm).

The resulting densities of catch at size were converted into densities of catch at age using an inverted growth equation. Annual age length keys do not exist for this stock for use in converting catch at length densities into catch at age densities. For the purposes of computing age, the time of spawning (birthdate) and the approximate time of laying down annuli (marking) were assumed to occur at the same time of the year (March to April) based on information on growth and reproductive condition obtained from the literature. The growth studies of Burch (1979) and Manooch and Potts (1997) both indicated that annuli were formed during the spring months from March through April, in greater amberjack and Burch also showed that gonad development was maximum around this same time. There is no new information to refute the Burch study.

The growth equation parameters used to convert length densities to age densities, those of Manooch and Potts (1997) were the same values as used in the previous 1996 assessment however the information was preliminary at the time of the 1996 assessment and not in the published literature ($k = 0.115$, $L_{\infty} = 1,514$ fork length (mm), and $t_0 = -1.178$). The Manooch and Potts (1997) parameters were used in this study over those of Burch for describing the growth dynamics and for estimating age from length of the Atlantic greater amberjack stock for three reasons: 1) the results are more recent than the Burch study which was conducted in the mid 1970's and growth may have changed in the period between, 2) the results were based on otolith readings which have shown to be necessary for this hard to age species, and 3) although Manooch and Pott's study is considered limited in terms of the total number of fishes ages ($n=155$) fish were sampled from a wider geographical coverage, North Carolina through the Florida Keys, than in Burch's study and included samples from headboats as well as commercial handline vessels thus including fish of larger sizes, in their growth calculations than for example, did the previous greater amberjack growth study of Manooch and Potts (1997) which only sampled headboats in the Gulf of Mexico. This study contained fishes from 442 mm through 1365 mm fork length whereas the Burch study included fish ranging in size from 256 mm to 1,435 ($n=343$, length range represents average).

Current Fishery Statistics

Commercial Landings

Over the 37 calendar year period, 1962 through 1998, reported commercial landings of the Atlantic greater amberjack stock ranged from 6,344 (1962) to 2,332,479 pounds (1991) (Table 1a, Figure 1; Appendix Table 1FY, Appendix Figure 1FY). The 1998 landings data are preliminary. There is good anecdotal information to explain the

explosive increases in reported landings during the mid 1980's. Increased consumption of greater amberjack as an edible foodfish and usage of this species by restaurants as a substitute for redfish in the blackened fish restaurant market occurred (see Berry and Burch 1978). In addition, in the mid to late 1980's, hook and line fishermen shifted to targeting greater amberjack from other fisheries (snapper and grouper and king mackerel) on the Florida east Coast (Hartig 1991). Hartig (1991) further noted the sinking of two barges off Palm Beach, Florida Inlet in the fall of 1989, thought to be large attractors to jacks. Reported commercial landings declined from 1991 through 1993, remained stable at about 1.9 million pounds through 1995, and declined through 1998. Potts et al. (1998) also reported the stable trend in commercial landings from 1993 through 1995.

The reported commercial landings data show as in earlier reports that the Atlantic stock is landed commercially for the most part in Florida with significant quantities of this resource being caught in the Florida Keys and landed in Monroe, County (Florida) (Table 1b). Between 1986 and 1989 there were some catches landed in Florida and trucked to inland points for subsequent sale; these landings are labeled (Table 1a) as Florida inland landings and generally have not occurred in later years. The 1998 reported landings are 19.6% lower than the reported landings for 1997. The distribution of commercial landings by major gear category and by statistical grid of capture was reviewed. As in previous years reports, the major gear used in capture is hook and line and also that greater amberjack are caught mainly off the Florida east coast (Table 2 and 3 and Figures 2 and 3). The monthly distribution of landings from North Carolina through Monroe County, Florida is presented in Table 4 and Figure 4. Month was un-recorded on the commercial landings records before 1977. This table indicates as in previous examinations of the landings data that March through June are the main landings months contributing on average 56% of the total annual landings. This is not un-expected as these months are presumed to be during the peak of spawning for this species in the Atlantic (Burch 1979).

Total Recreational Harvest (A+B1 Catch) By State and Fishery

Total estimated recreational harvest (A+B1) of the greater amberjack stock in the Atlantic Ocean ranged from 14,911 (1982) fish to 100,326 fish (1987) from 1981 through 1998. The recreational harvest, A+B1, includes catches by private anglers, shore fishermen, charter boats, and headboats (Table 5, Figure 5). Traditionally shore and headboat anglers have made up a small percentage of the anglers catching greater amberjack. As reported by Cummings and McClellan (1996) most of the recreational harvest, A+B1, comes from Florida anglers (Table 6, Figure 6a; Appendix Table 2FY, Appendix Figures 2Fy, 3aFY). Greater amberjack have been caught ore often by charterboat anglers since about 1991 than by private or headboat anglers (Figure 6b, Appendix Figure 3b). The breakdown of recreational harvest by state, fishery, and fishing year is given in Table 6 and Appendix Table 2. Interestingly, based on a survey of charterboats sampled off Dade County, Florida from May 1970 through April 1978, Berry and Burch estimated that 85% of all amberjack landed were caught by charterboats.

The overall trend of estimated Atlantic greater amberjack recreational harvest, A+B1, of the Atlantic greater amberjack stock is a declining one that began around 1987. This

pattern is complicated however; by apparently large increases in the charterboat sector catch estimates for 1987 and 1994, and in the private boat fishery in 1996 (Figure 6b). The large increases in recreational catch around 1994 and 1996 are not as prominent when the data are summarized by fishing year and fishery (Appendix Figures 3a,bFY). The pattern of A+B1 harvest across all sectors shows a decline occurring between fishing year 1987 and 1990, a non-varying trend in A+B1 harvest from 1990-1995 and a decline since 1995. Both the calendar year and fishing year summaries show an increase in catch occurring in 1987 and in 1989 on the East Coast of Florida, as was indicated with commercial landings. The charterboat fishing year summary indicates an increase occurred in the 1989 fishing year. The increase in the estimate of charterboat catch reported for the 1994 calendar year is apparent in the 1993 fishing year; the following (fishing) years however indicate a gentle decline in estimated A+B1 harvest. The private boat fishery fishing year summaries suggest that the estimate of A+B1 catch, increased through fishing year 1989 and declined in 1990. The pattern of private boat catch is not clear after 1990 however, as the estimates show several years of increases followed by declines in estimates of catch, A+B1, and then increases again in the estimates of A+B1 harvest (Appendix Figure 3a, 3b).

There is good reason to be cautious when discussing trends in the private and charterboat sectors, and in estimates of total recreational harvest, as the variance estimates of the MRFSS catch estimates are very large in some years (see Table 5). The large variability in estimated recreational catch was also apparent in the estimated trajectory of recreational landings by charter boats reported by Potts et al. (1998). Potts et al. (1998) show a similar trend in rising recreational landings (in weight) in the mid 1980's peaking in the early 1990's and declining since 1991. The increase recreational catch estimates occurred at about the same time, mid to late 1980's, as did increasing commercial landings.

Distribution of Recreational Harvest (A+B1 catch) by Two Month Wave and By Fishery

The proportional distribution of recreational A+B1 harvest of greater amberjack caught in the Atlantic Ocean is shown by two month time period (wave), by state (and for all states combined), and by calendar year (Figure 7). These plots again show as with the commercial landings that the majority of estimated A+B1 harvest comes from spring and summer months in all years. In Florida, these distributions show that a moderate level of recreational effort for this species occurs year round unlike for example in Georgia where the catches are small except during May- June and some fall activity in the later years. Winter recreational catches of greater amberjack off Georgia are very low in comparison to Florida. In the Carolinas, recreational catches occur mainly during the late summer and fall months. The pattern provides support for the hypotheses made regarding greater amberjack making fall migrations up the Atlantic east coast during fall months and southward from the Virginias into Florida during spring (McClellan and Cummings 1997). These distributions also provide researchers with information that shows historically when recreational effort may have occurred in a specific area (state) although it not known whether the effort was directed at this species.

The distribution of the recreational A+B1 harvest A+B1 across each two month wave (time period) is shown for each fishery and the distribution of harvest (A+B1) across fisheries within a two month wave (time period) is given in Figure 8a. These distributions give some idea as to when a particular sector has the greatest impact on recreational greater amberjack catches in the Atlantic Ocean. The charterboat sector dominates all time periods except late summer and early fall when the private boat fishery takes more catch on average across all years (Figure 8b). These plots also indicate that private boat and charterboat anglers have caught greater amberjack year round with late summer being the lowest period for charterboat anglers and late fall the lowest catch period for private boat anglers. Private boat fishermen are known to fish the fall migration of king mackerel as they move up the coast off the Carolinas. In addition, many fishermen have traditionally fished the fall spawning aggregations of reef fishes including mutton and yellowtail snapper, activity which might explain lower private boat catches of greater amberjack during the fall months. Figure 9 show the percentage breakdown of recreational harvest, A+B1, by calendar and distance off shore (Ocean zone). In nearly all years the majority of the estimated recreational greater amberjack in the Atlantic Ocean has been taken from federal waters.

Estimated Total Recreational Catch: A+B1 Harvest and B2 Releases by Fishery

Changes in recreational regulations that have been adopted since the Cummings and McClellan (1996, 1997) reports include the adoption of a one fish per person per trip bag limit in Monroe County, Florida for all amberjack species. This regulation in addition to the three fish per person per trip bag limit and to the 36" fork length minimum size limit implemented in 1991 for federal waters should be considered with any discussion of trends in recreational catch. The quantity of greater amberjack being released was of interest here because of the recent regulations regarding the 3 fish bag limits and also the 28 " fork length minimum size limit.

Estimates of the number of the Atlantic greater amberjack caught and released, referred to as B2 catch, existed from the MRFSS survey. Estimates of releases were not available for the headboat fishery. Between 1981 and 1985 catch estimates for the charterboat and headboat (party) were combined therefore releases of greater amberjack by charterboat fishermen are presented only since 1986. Over the period 1981 – 1998 charterboat anglers released on average 17 % of their total catch ranging from 6.5% to 30.1 % annually (Table 8, Figure 10; Appendix Table 3FY). The percentage of fish released from the charter boat fishery was fairly consistent across all years. Anglers fishing from private vessels released on average 49 % of their catch however, the annual percentage of the total catch that was released was more variable ranging from 31 % to 83 % and show the highest percentage of releases occurring in more recent years. The total number of fish caught, A+B1+B2 and the estimated number of releases, B2, is given by two-month wave (time period) in Figure 11. These results indicate a significant number of fish are released between May and August. Table 9 shows the distribution of releases within fishery across two-month wave period showing that during the spring and summers months the charterboat fishery releases the most fishes percentage wise. The pattern of releases is similar for the fishing year summaries. Figure 12 shows the distribution of total catch, A+B1 harvests + B2 releases, by calendar year.

The summary information pertaining to the pattern of the B2 catch, the estimated number of greater amberjack caught and released in the Atlantic Ocean, when combined across fisheries with the A+B1 harvest, also shows declines in A+B1+B2 total catch of greater amberjack (Table 9, Figure 11 and 12; Appendix Figure 4FY). Apparent also is an increasing trend in the number of releases, B2, between 1985 and 1993. The pattern of total estimated catch, A+B1+B2, shows a large catch decline in calendar year 1995 which seems anomalous because the 1996 estimate is about the same level as the 1991, 1992, and 1993 calendar year levels. The annual pattern of estimated total catch (A+B1+B2) indicates large declines for calendar years 1997 and 1998. The complimentary fishing year summary (Appendix Figure 5FY) however, indicates a gentle decline in total estimated catch, A+B1+B2, starting in 1993 that continues through the 1997 fishing year with the estimates of the largest declines for the private boat fishery and occurring since 1996.

Estimates of total recreational fishing effort from the MRFSS survey (Appendix Figure 6FY), which includes fishing activity of all anglers were available. These estimates were considered in trying to understand the pattern of recreational catches. The summary trip estimates indicate total estimated private angler effort increased by about 2.5 times between fishing year 1986 through fishing year 1988 declined through fishing year 1990 by about 1/3, varied without trend through the 1995 fishing year and declined again in 1996 (Figure 6a). Estimated effort by charterboat fishermen also increased between 1987 and 1988 fishing year and then declined by about half, through 1990 and the estimate of total charterboat effort has varied without trend since.

Greater amberjack Catch Sample Size Frequency Data

The individual length frequency samples available for the Atlantic greater amberjack stock were replaced in total from the same data sources as used in the earlier assessments. The majority of samples were from the NMFS Trip Interview Program, the NMFS Beaufort Laboratory Headboat Survey, the MRFSS database, and the NMFS, Panama City Laboratory. Some additional samples also existed from the Biscayne National Park sampling program, which intercepts private boat fishermen off Miami, Florida. The number of individual length measurements by year, state of collection, and fishery is given in Table 10. In general the Atlantic greater amberjack fisheries were not sampled to any large degree (Table 10) until the mid 1980's although this stock has been heavily exploited since the early 1950's (Berry and Burch 1978). The availability of catch samples for the dominant gear types used in exploiting the Atlantic greater amberjack stock are described below.

Commercial Handline

The commercial Handline fishery was sparsely sampled until 1991; in all years before 1991 from 1 fish to 201 fishes were measured for length. From 1991 through 1998 from 413 fish to 1,409 fish were measured annually across all states where Atlantic greater amberjack were landed. Most samples were taken from vessels landing greater amberjack catches off the Florida East Coast and in the Florida Keys (Table 10). In 1995 sampling declined to a very low level in Monroe county, Florida and did not return to the

previous year's level until 1997. The states of South Carolina followed by North Carolina dominate the landings of commercial vessels landing Atlantic greater amberjack after Florida (see Table 2). Until 1996 however, less than 100 fish were measured for length in South Carolina and in North Carolina on average about 50 greater amberjack were measured annually. Because the total number of samples were so few, and the total number of individual measurements, and these samples were restricted temporally across months of the year (Table 10), it was not possible to assign samples at the monthly level. However, where the total number of measurements was near 100 fish for a state and the annual density did not appear truncated, samples were assigned at the state level to commercial Handline catches. Table 10 also shows that sampling of the commercial Handline catches increased between 1996 and 1998 indicating some improvement in data acquisition for this fishery since the 1996 Cummings and McClellan study. A detailed listing of the protocol followed for assigning samples to each fishery, area (state), year commercial Handline landing is given in Appendix 7.

Commercial Bottom Longline Samples

Greater amberjack have been reported landed by commercial vessels using bottom longlines since about 1982 annually in small quantities less than 1000 pounds; and annually since 1986 about 20,000 to 30,000 pounds were landed annually (see Tables 2 and 3c). The observed length distribution of greater amberjack landed by bottom longline was visually different from Handline caught fish, suggesting that fish caught by this gear were slightly larger than fish caught on handlines, therefore maintaining gear in the sample assignments seemed important. Since 1988, 402 fish were measured from bottom linguine catches. The 1992 and 1993 bottom linguine samples were assigned to bottom longline catches; in all other years it was necessary to pool samples from bottom longline with commercial Handline samples. About half of the bottom longline samples were from Florida and the remaining half distributed over the Carolinas and Georgia however, the coverage was too sparse to allow assigning at the state or a finer gear level. Appendix 1 gives details on the protocol used in assigning commercial samples to bottom longline catches.

Commercial Dive Samples

Since about 1986, substantial quantities of the Atlantic greater amberjack stock have been landed by commercial vessels using spearguns or powerheads (see Tables 2, 3d). These catches were sampled infrequently and only since 1991 although this gear is the second in importance in exploiting this stock since about 1987 with most dive catches being taken off Florida (see Table 3d). The 1993 and 1996 commercial dive samples were assigned to dive catches however as with bottom longline catches, it was necessary to use samples commercial handline catch samples in addition to dive catch samples in all other year for estimating the catch at size. Most of the dive samples were from Florida and Georgia. Appendix Figure 7 gives details on the protocol used in assigning commercial samples to dive catches.

Recreational Charter, Private, and Shore Catch Samples

The distribution of the Atlantic greater amberjack catch length frequency samples for the recreational fishery (Table 10) were examined with respect to fishery (charter, private, shore), year of sample, and the state of intercept (i.e., Florida East coast, Monroe

county, Florida; Georgia, South Carolina, and North Carolina). Since 1981, nearly 1,700 fish were measured for length with most samples coming from the charterboat fishery ($n=1,279$ lengths) followed by the private boat fishery ($n=387$ lengths), and then the incidental shore catches ($n=25$ lengths).

The summary statistics from Table 10 show that since 1996 MRFSS length frequency sampling did not increase for the Atlantic greater amberjack in the private boat fishery and shows only a small increase in 1998 in the charterboat sector. The distribution of MRFSS samples collected by state (Table 10) is consistent with the information presented by Cummings and McClellan (1996). In many year-state cells only one fish was sampled in the private boat fishery. The two highest years of sampling was 1981 ($n=55$ lengths) and 1996 ($n=37$ lengths). In some states the private boat fishery was rarely sampled, in other years not at all. Catches of greater amberjack by this sector however have been substantial over the period, 1981-1998 and, infact many private boat fishermen have registered concern with fisheries regarding the status of the stock (Amend. #9, SG-FMP).

In most years the number of lengths sampled from charterboat catches was fewer than 100 in any state (Table 10). In 1987, 1989, 1991-1994 and in 1998 charterboat samples were assigned separately to charterboat catches. In other years private boat catch samples were used as well. Too few samples were collected for the private boat fishery in any year to consider assigning samples at the fishery level therefore, charterboat samples and private boat samples were pooled for the purposes of catch at size estimation. Samples were always combined across states since the number of lengths was less than 50 lengths at the state level. The number of recreational lengths for South Carolina was low in general; however, the absence after 1994 seems suspects. Appendix Figure 8 gives a detail accounting of the protocol used in assigning recreational samples to recreational catches for all fisheries.

Recreational Headboat Catch Samples

Recreational catch length frequency samples from the headboat fishery were considered separately because of operational differences between headboats and other recreational modes (i.e., charter, private). In addition, previous studies (Cummings and McClellan 1996, Potts et al. 1997, 1998) have shown differences between the sizes of greater amberjack caught by headboat anglers and those caught by charterboat or private boat recreational fishermen. Visual inspection of the length densities (Figure 13) indicated that traditionally headboat anglers have landed smaller fish than those caught and landed by anglers fishing from charterboats and/or private boats.

Samples from headboat catches were sufficient from the Florida East Coast in 1981, 1983-1987, and in 1989 to assign samples at the state-year resolution level. Headboat catch samples were pooled across state in all other years for use in catch at size estimations. The sample length frequency statistics (Table 10) show that headboat sampling declined since the earlier 1996 assessment and infact the number of samples in 1997 was about 70% lower than the level of 1987. Greater amberjack headboat catches in Georgia have traditionally been very low (see Table 6). Greater amberjack headboat

sampling in the Carolinas has varied without trend, while the number of lengths sampled in Florida has consistently declined over all since the late 1980's. Headboat catches of greater amberjack are highest in Florida.

Estimated Total Catch at Size and Total Landed Catch At Age

The results of the catch at size estimations were reviewed with respect to the sufficiency of samples available to characterize the catch dynamics with respect to time period (year) and geographical location (state) for each fishery. The sampling was considered sufficient only since 1987 for purposes of estimation of total catch. Prior to that year the commercial fishery was not sufficiently sampled. Therefore the history of estimated catch at size and estimated catch at age for subsequent analyses related to stock assessment only considered the calendar years 1987 and forward.

Estimated total commercial catch at size for the Atlantic greater amberjack stock is presented in Figure 14 and Table 11 for the three main commercial gears. Gears that made incidental catches of greater amberjack (i.e., trap, fish trawl, seine, etc.) are shown in these distributions as "commercial other gears". The length distributions of the estimated commercial handline catch between 1987 and 1991 indicate a substantial amount of small fish were landed prior to the minimum size regulation was adopted in 1992. These plots do not show reveal distinct size modes in many years. The size distributions for the 1993 and 1996 dive catches (Figure 14b), the only two years considered sufficient in terms of sample size to use at the gear specific level, provides some information to suggest that this fishery exploited a more restricted size range of greater amberjack than did the handline fishery.

Estimates of the total landed catch at size, A+B1, for recreational catches of greater amberjack in the Atlantic Ocean are presented in Figures 15 and 16 and Tables 12 and 13. The plots for the charterboat catch (15a) and the private boat catch (15b) are not very dissimilar in some years, revealing the pooling effect of having to assign charterboat samples as well as samples from the private boat fishery to apportion the catch over length.

The total estimated landed catch for the Atlantic greater amberjack stock for the three main fishery types, commercial, recreational, and headboat is presented in Table 14 and Figure 17. Estimated total yield landed (reported commercial and estimated recreational) is given in Table 15 and Figure 18.

Total Landed and Discarded Catch

Further evaluation of the status of the Atlantic greater amberjack made use of the catch at age estimated in this study and Virtual Population Analyses. VPA analyses require that the total removals be known in order to estimate stocksizes and fishing mortality rates. To accurately reflect the total removals of the recreational catch of the Atlantic greater amberjack the estimated catch of releases, B2, catch (see Table 8) were used. Limited information exists to document the quantity of fish that die after release. Preliminary information from a small study ($n=23$ fish released) conducted under optimal conditions indicated that survival for fish released from headboats was fairly high, 91%, (Manooch pers. comm.) however, this rate seemed high. A 20% mortality figure was

assumed and applied to the estimated B2 catch (see Table 8) and the resulting discarded catch distributed equally across all ages in the recreational MRFSS catch. A review of the individual observations of catch per angler in the MRFSS intercepts indicate that catches larger than the 3 fish per person bag limit (enacted in 1992) have continued to occur after the regulation (Figure 19). This provided some support that the size distribution (and age) of the B2 catch may not be entirely limited to fish below the minimum size therefore the fractional portion of the B2 catch assumed to die (20%) was distributed across all ages.

It was noted that after 1992, the estimated commercial and headboat catch at length distributions (see Tables 11-13 and Figures 14-16) suggested that the distribution of small (young) fish in the catch was not the same as before the size regulation went into effect. Information regarding the size of fish that may be released by either of these fisheries, either because of minimum size regulations for the commercial fishery or because of size limit restrictions and/or bag limit restrictions in the case of the headboat fishery was unavailable. Port agents were contacted and the operating practices of the commercial handline fisheries discussed as pertains to releasing fish. It was generally thought that releases if made in the commercial fishery, would most likely be fish less than the minimum size. Therefore, it was assumed that the average fractional proportion of the catch at age prior to the regulation, 1987-1991, was the same as the average fractional proportion of the catch at age after the regulation. The catch at age for each year was then adjusted upwards by the difference in the proportions at age between the two periods (Table 16). This catch, referred to as the discarded catch, was estimated for ages 5 and lower for the commercial fishery and for age 4 and below for the headboat fishery. The estimated total directed catch at age for the Atlantic greater amberjack stock, including discards, is presented by fishery (commercial, recreational, and headboat) and for all fisheries combined in Figures 20 and in Table 17).

Stock Evaluation Concerns

The Atlantic greater amberjack estimates of total catch at age, landed plus discarded, (Table 17, Figure 20) were used in conjunction with standardized indices of abundance developed for this stock (see Cummings et al. 1999) in subsequent analyses that evaluated the status of the stock. Those analyses used VPA techniques and incorporated uncertainty regarding greater amberjack biological parameters into calculations of stock sizes and future allowable biological catches. In addition to requiring information on removals, measures of abundance for purposes of tuning, these procedures also require information on maturation size, fecundity at size or age, and natal mortality (M). The biological literature for the greater amberjack was reviewed with respect to these biological parameters.

Potts et al. (1998) gave a range of values for M , calculated using eight different methods, several that made use of growth parameter estimates and several incorporated information regarding environmental parameters including Pauly's (1980) approach using temperature. These methods are dependent on the growth information for computing the growth rate parameter, k and that the study is reflective of all ages in the population. Estimates of M from the independent methods ranged from 0.14 to 0.55 (Table 18). Two

estimates were below 0.2 and five of the eight were below 0.3. The mean calculated M value for the three studies that incorporated growth information and also environmental data was 0.20. Cummings and McClellan (1996) used a value of M=0.3 in their preliminary VPA analyses. Potts et al. (1998) calculated the spawning potential ratios (SPR's) using two values of M, 0.2 and 0.25. Further analyses of the Atlantic greater amberjack examined the stock status used 0.25.

SPR is defined as the ratio of the number of eggs that could be produced by an average recruit over its lifetime when the stock is fished divided by the the number of eggs that could be produced by an average recruit over its lifetime when the stock is unfished. SPR is often referred to as comparing the spawning ability of a stock in the fished condition to the stock's spawning ability in the unfished state. The Atlantic greater amberjack stock is presently managed by using a 40 % static SPR ratio.

Fecundity at size data do not exist for the Atlantic greater amberjack from any study. Burch (1979) evaluated gonad condition in fish collected from south Florida and found that maximum gonad development occurred in the spring months however, that study did not carry out microscopic evaluations of the gonads.

Reliable information on maturation is critical as the choice of age at maturity can have an impact on the resulting SPR value. Studies providing theoretical SPR's for the Atlantic greater amberjack have used weight at age information in the absence of fecundity at size (age) data assuming that 50% sexual maturity in Atlantic greater amberjack occurs at age 3 (see Huntsman et al. 1992, 1993a, 1993b and Potts et al. 1998). The use of age 3 as the current maturation age for this stock has some support based on observations of the sizes of ripe fish and the estimated size at age from growth studies.

Burch's (1979) south Florida study and Thompson et al.'s (1991) study for fish collected off Louisiana provide the only information on maturation of the greater amberjack of the southeastern U.S. Burch's study reported that all fish were mature by their fourth year which corresponded to an estimated Von Bertalanffy size range of 77 cm – 91 cm fork length or to a size range off his scale readings of 80 cm – 91 cm fork length (Figure 21). Burch reported below about 50 cm fork length sex determination in greater amberjack was not possible and further that some fishes were mature by the third year of life, corresponding to a Von Bertalanffy estimated size range of 61 cm – 77 cm fork length according to Burch's growth parameters (see Figure 21). Manooch has also reported that Atlantic greater amberjack mature by their third year of life (Manooch pers. comm.). This information, based on fish sampled nearly 23 years ago, suggests that Atlantic greater amberjack mature from age 3 to 4 and all fish are mature by age 5.

The Thompson et al. (1991) study, some 20 years later, provides comparative data on maturation in this species from another region. Although Thompson's two-year study was hampered by a large number observations of ovaries that appeared to be infected with an unknown pathogen some information on maturation was still obtained. Thompson reported as did Burch (1979) that gonad development was maximum during spring, mainly between May and June. These investigators also reported that greater

amberjack sampled in their study matured between 93 cm and 96 cm fork length and their maturity determinations were all based on histological examinations. Based on their growth determinations made using sectioned otoliths they postulated that the age of maturity was age 2 to 3. Beasley et al. (1996) provide good support regarding the size at age information from the Thompson et al. as ages 2 and 3 (see Figure 21) were verified through oxy-tetracycline marking experiments. Cummings and McClellan thus used age 3 as the age of knife-edge maturity in their analyses of the Gulf of Mexico greater amberjack stock involving SPR calculations.

Neither the Burch (1979) study nor the Thompson et al. (1991) study provides definitive information on the maturation age of the greater amberjack. The Gulf of Mexico study may not be applicable to fish from south Florida and fecundity at size (age) was not determined. In addition, maturation may have changed in the Atlantic since Burch's study however, neither of the studies provide any scientific support to suggest that the age of 50% maturation in the Atlantic greater amberjack is currently beyond age 5.

Acknowledgments

Josh Bennet and J. Poffenberger provided commercial fishery statistics. Patty Phares provided all data pertaining to the recreational and headboat fishery. Charlie Schaeffer and Rick Beaver provided comments regarding changes in the operation of the recent commercial fisheries. Chuck Manooch answered many questions related to growth and maturation in this species. Steve Turner provided helpful comments on the manuscript. Thanks are extended to these individuals for their timeliness.

Mean: Hoenig, Pauly, and Alagaraja	0.20

Figure 1. Reported commercial landings by calendar year for Atlantic Ocean greater amberjack in the southeastern United States, 1962-1998. Landings from the Florida Keys are included in the Atlantic stock. The 1998 values are preliminary. Units are whole weight (pounds).

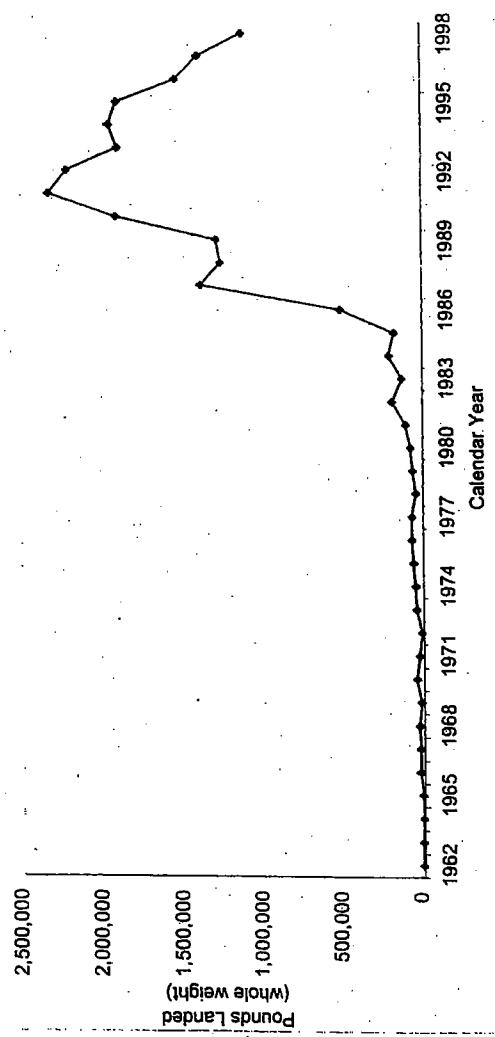

Figure 2. Reported commercial landings by gear type and calendar year for Atlantic Ocean greater amberjack in the southeastern United States, 1962-1998. The values for 1986 are preliminary. Units are in pounds (whole weight). Landings from the Florida Keys are included in the Atlantic stock.

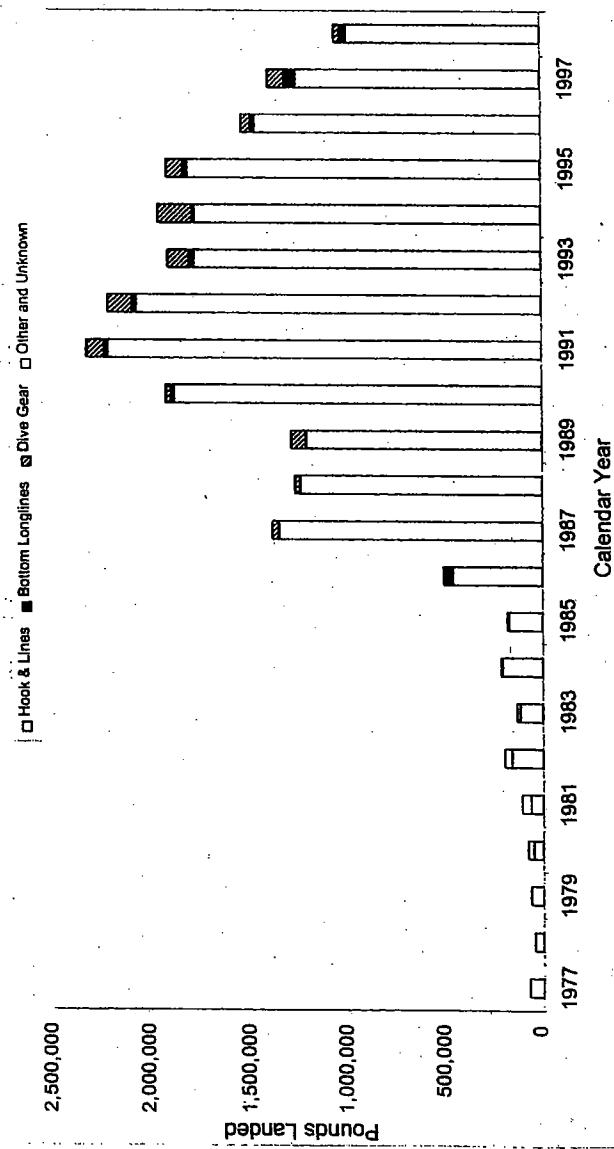

Figure 3. Spatial distribution of the reported commercial landings of Atlantic Ocean greater amberjack from the southeastern United States, 1977-1998 combined. Landings from the Florida Keys are included in the Atlantic stock. 1998 values are preliminary. Units are whole weight (pounds)

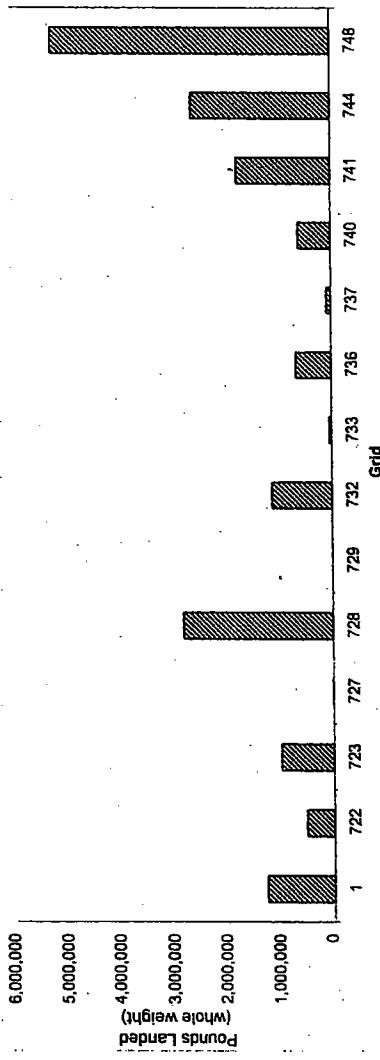

Figure 4. Reported commercial landings (percent) by month for Atlantic Ocean greater amberjack in the southeastern U.S., 1977-1998 combined. Landings for 1998 are preliminary. Landings from the Florida Keys are included in the Atlantic stock.

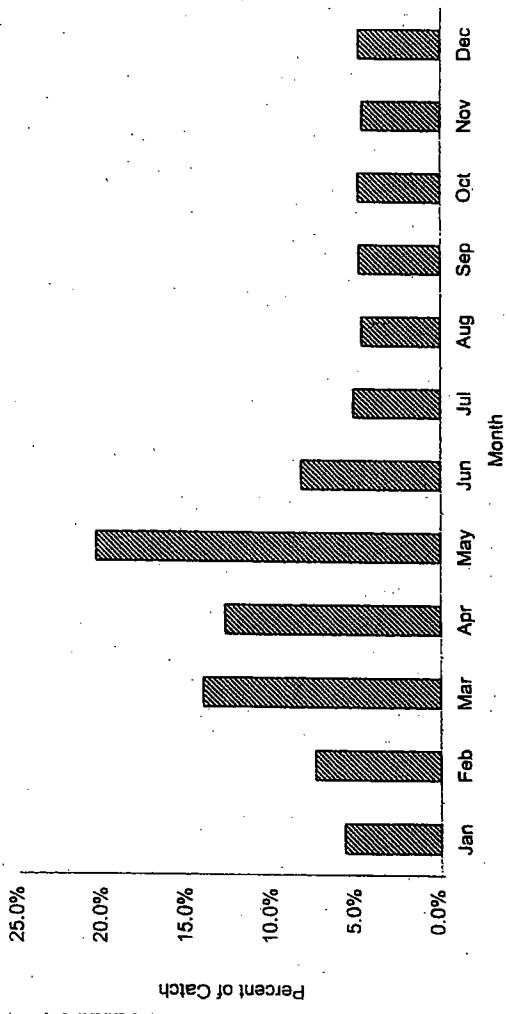

Figure 5. Estimated recreational catch (A+B1) of the Atlantic Ocean greater amberjack for the southeastern United States by source and calendar year, 1981-1998. Values for 1998 are preliminary. Units are number of fish. MRFSS includes Monroe county recreational catches (i.e., Florida Keys) in the Florida West Coast catch estimates; MRFSS estimates in this figure only include catches from Florida East Coast.

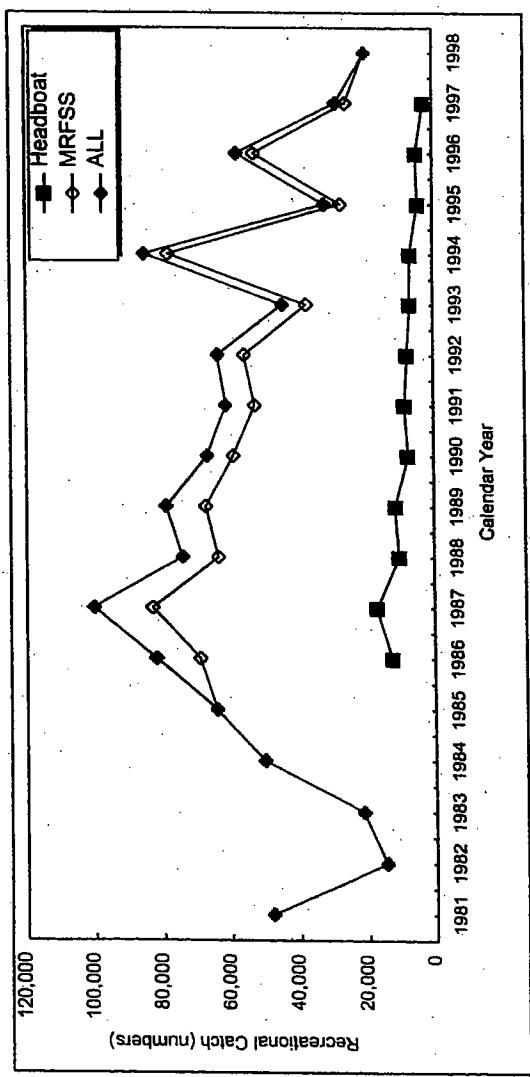

Figure 6b. Estimated recreational catch (A+B1) of the Atlantic Ocean greater amberjack for the southeastern United States by fishery and calendar year, 1981-1998. Values for 1998 are preliminary. Units are number of fish. MRFSS includes Monroe county recreational catches (i.e., Florida Keys) in the Florida West Coast catch estimates; MRFSS estimates in this figure only include catches from Florida East Coast.

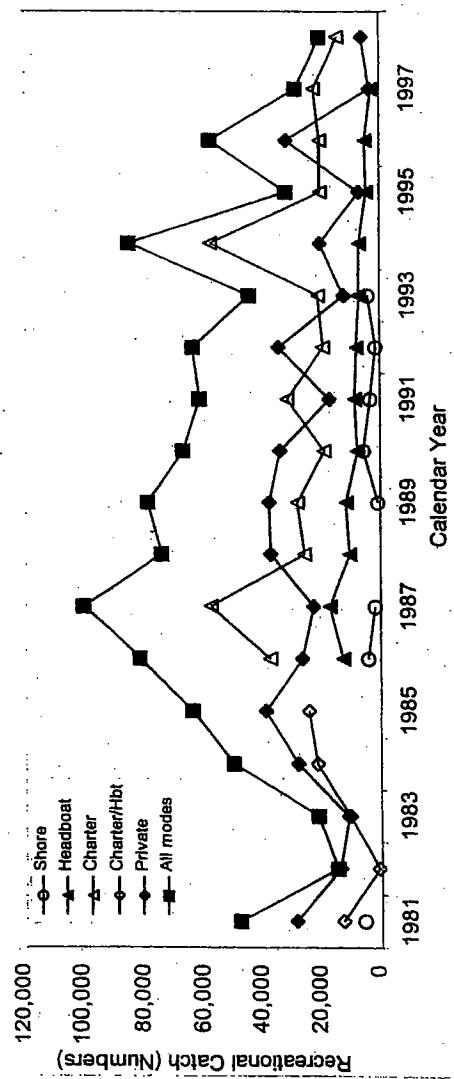

Figure 7. Proportion of recreational catch (A+B1) for Atlantic Ocean amberjack in the southeastern United States by two month wave and state based on MRFSS and NMFS Heedboat data. Values for 1988 are preliminary. MRFSS includes Monroe county recreational catches (i.e., Florida Keys) in the Florida West coast catch estimates; MRFSS estimates in this figure only include catches from Florida East coast.

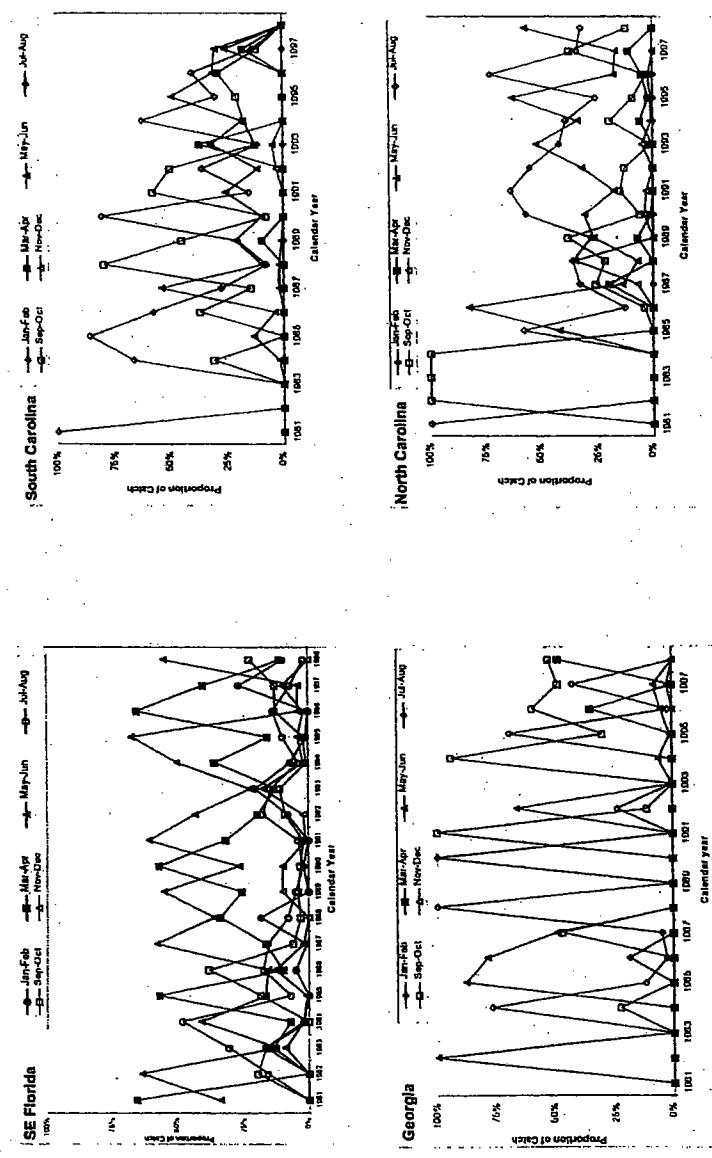

Figure 7. (cont.)

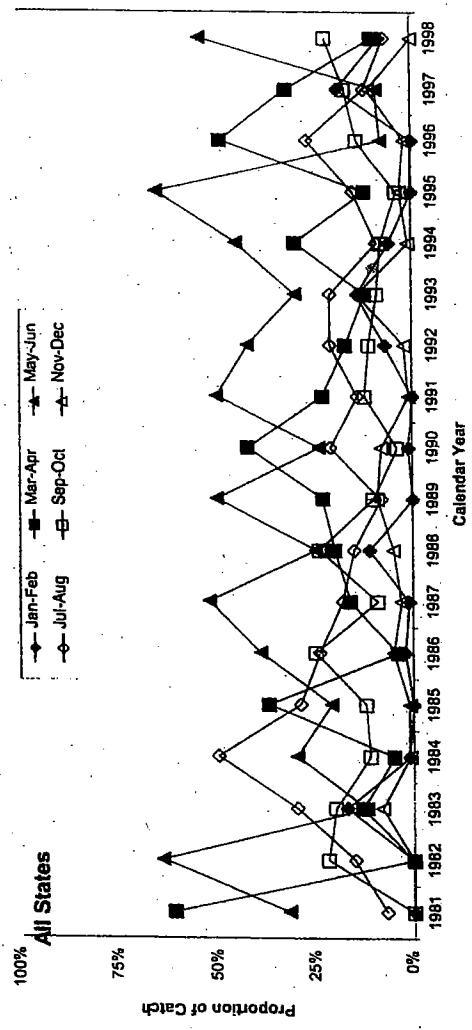

Figure 8. Distribution (percent) of Atlantic Ocean greater amberjack recreational harvest (A+B1) by mode (a) and two-month wave (b) based on MRFSS and NMFS Headboat data, 1981-1998. Values for 1998 are preliminary. MRFSS includes Monroe county recreational catches (i.e., Florida Keys) in the Florida West coast catch estimates; MRFSS estimates in this figure only include catches from Florida East coast.

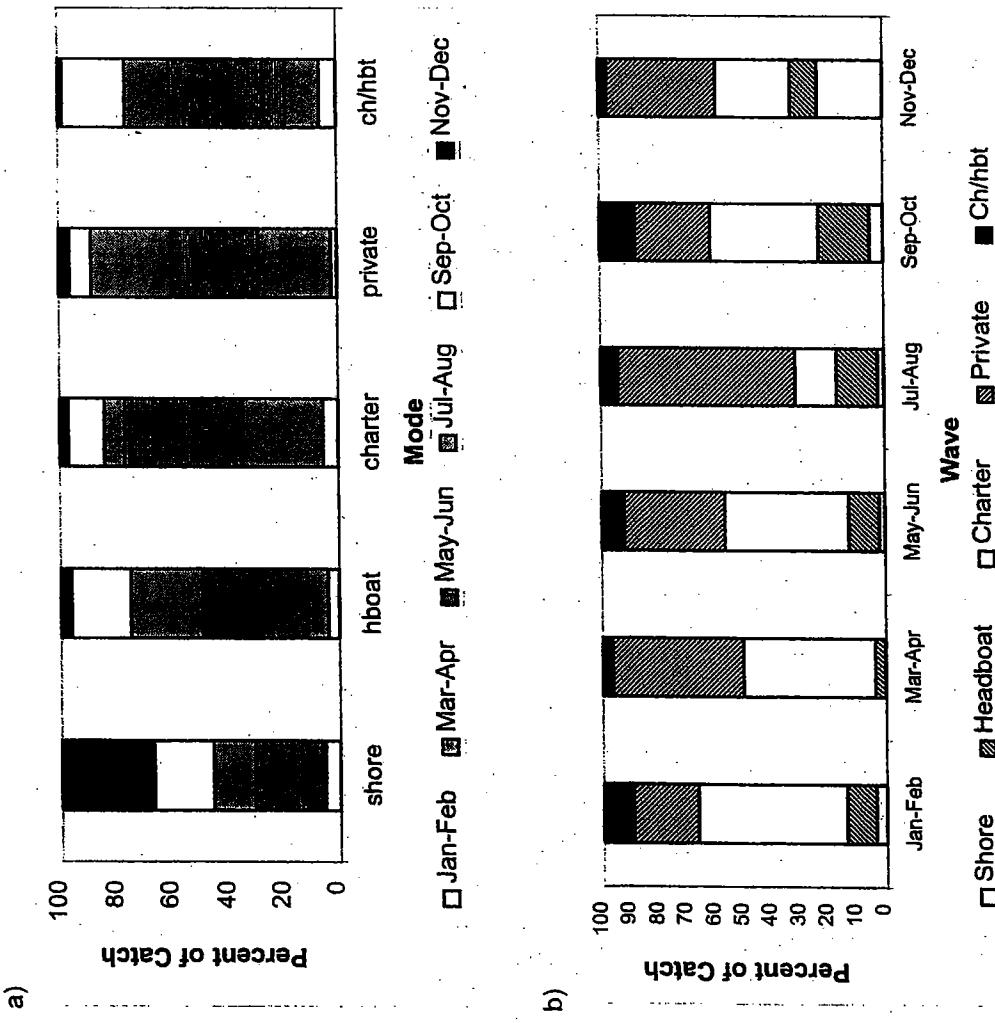

Figure 9. Estimated recreational harvest (percent, A+B1) of Atlantic Ocean greater amberjack by distance from shore and calendar year. Values for 1998 are preliminary. MRFSS estimates in this figure only include catches from Florida East Coast.

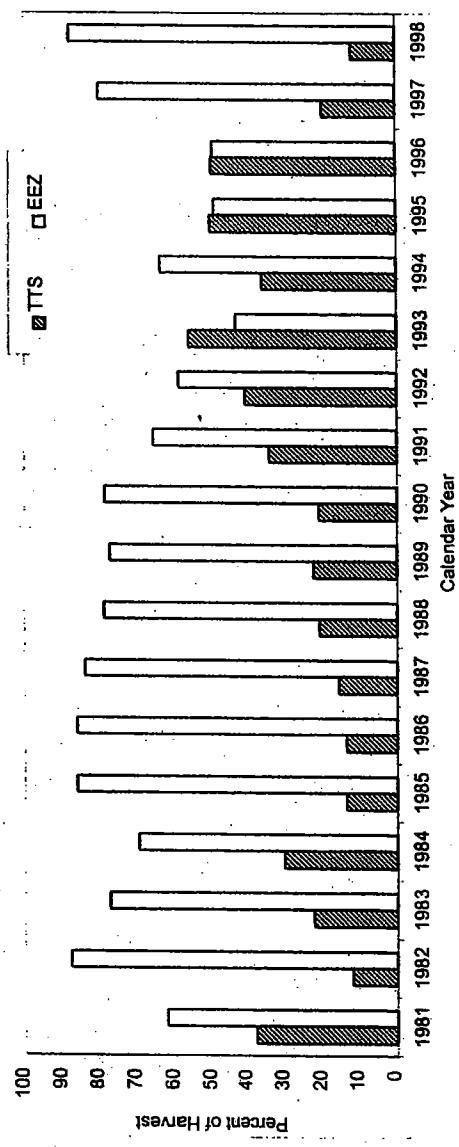

Figure 10. Estimated recreational harvest a) A+B1 and b) A+B1+B2 and disposition (percent released) of Atlantic Ocean greater amberjack by calendar year, based on MRFSS data. Values for 1998 are preliminary. Percent released equals number released (B2) divided by total caught (A+B1+B2). MRFSS includes Monroe county recreational catches (i.e., Florida Keys) in the Florida West Coast catch estimates; MRFSS estimates in this figure only include catches from Florida East Coast.

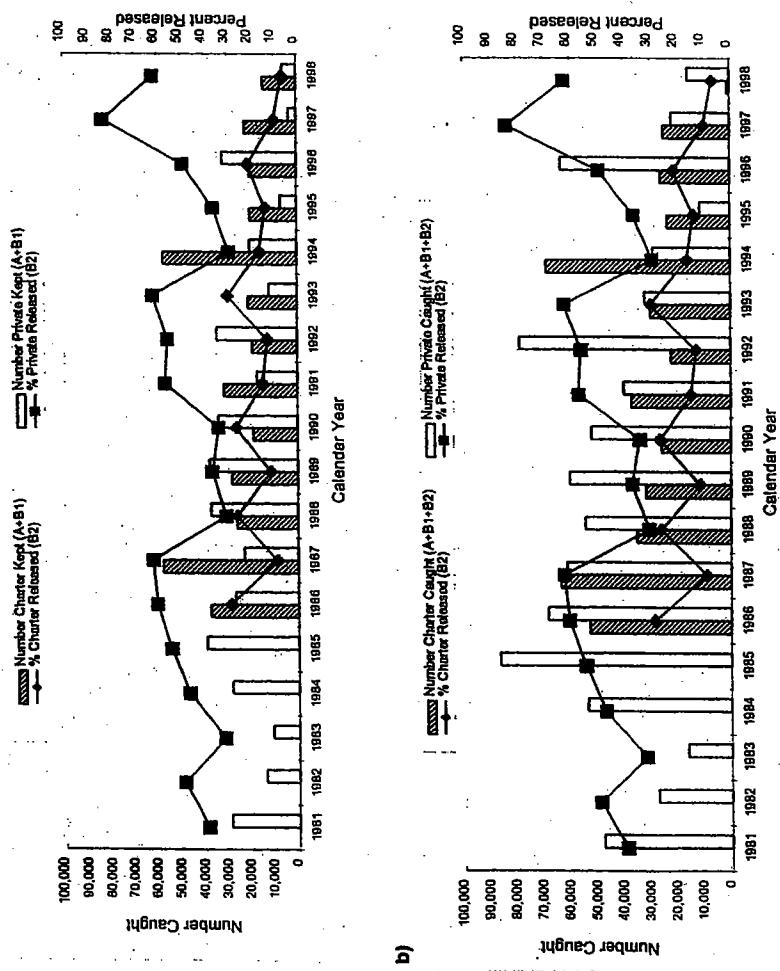

Figure 11. Recreational harvest of Atlantic Ocean greater amberjack (a) number released and total harvest and b) percentage of catch, by wave based on MRFSS data, 1981-1998 combined. Values from 1998 are preliminary. MRFSS includes Monroe county recreational catches (i.e., Florida Keys) in the Florida West Coast catch estimates; MRFSS estimates in this figure only include catches from Florida East Coast.

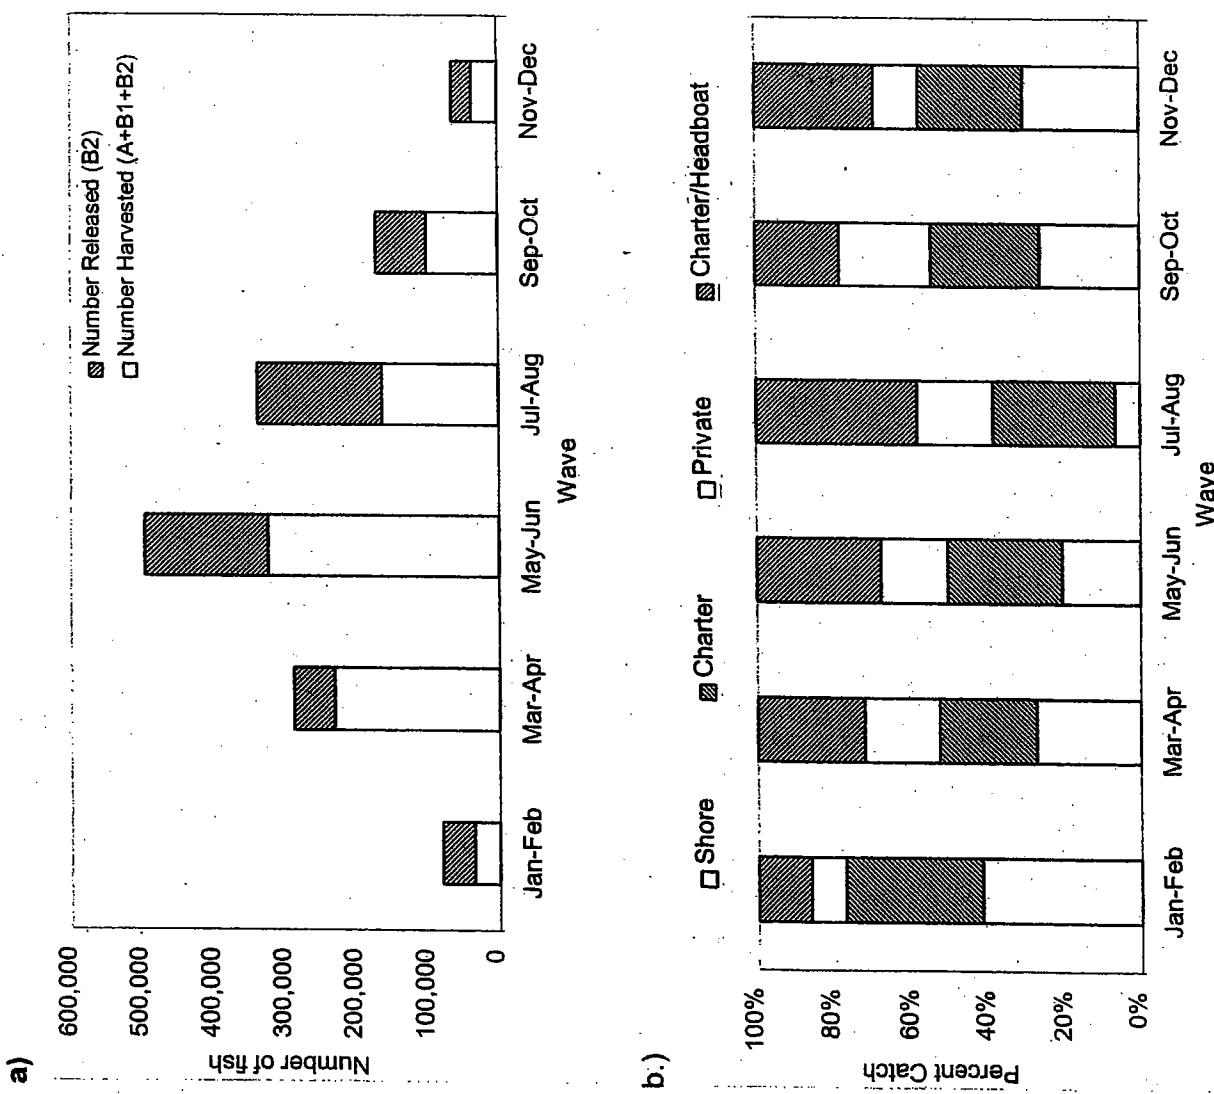

Figure 12. Disposition of greater amberjack caught by recreational fishermen from the Atlantic Ocean by all modes combined, 1981-1998 based on MRFSS data. Values from 1998 are preliminary
MRFSS includes Monroe county recreational catches (i.e., Florida Keys) in the Florida West Coast
catch estimates; MRFSS estimates in this figure only include catches from Florida East Coast.

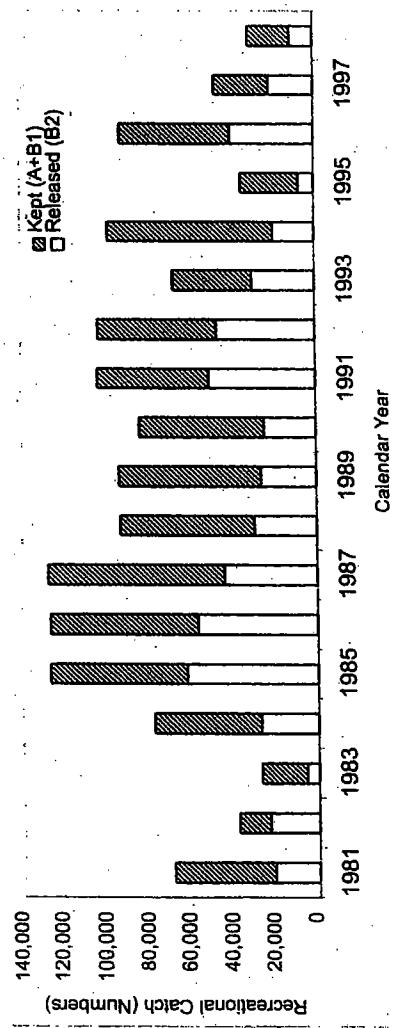

Figure 13a. Atlantic greater amberjack catch sample length distribution for the commercial handline fishery for all years combined. SECTOR=COM MODE=NEW=5, Gear is handline

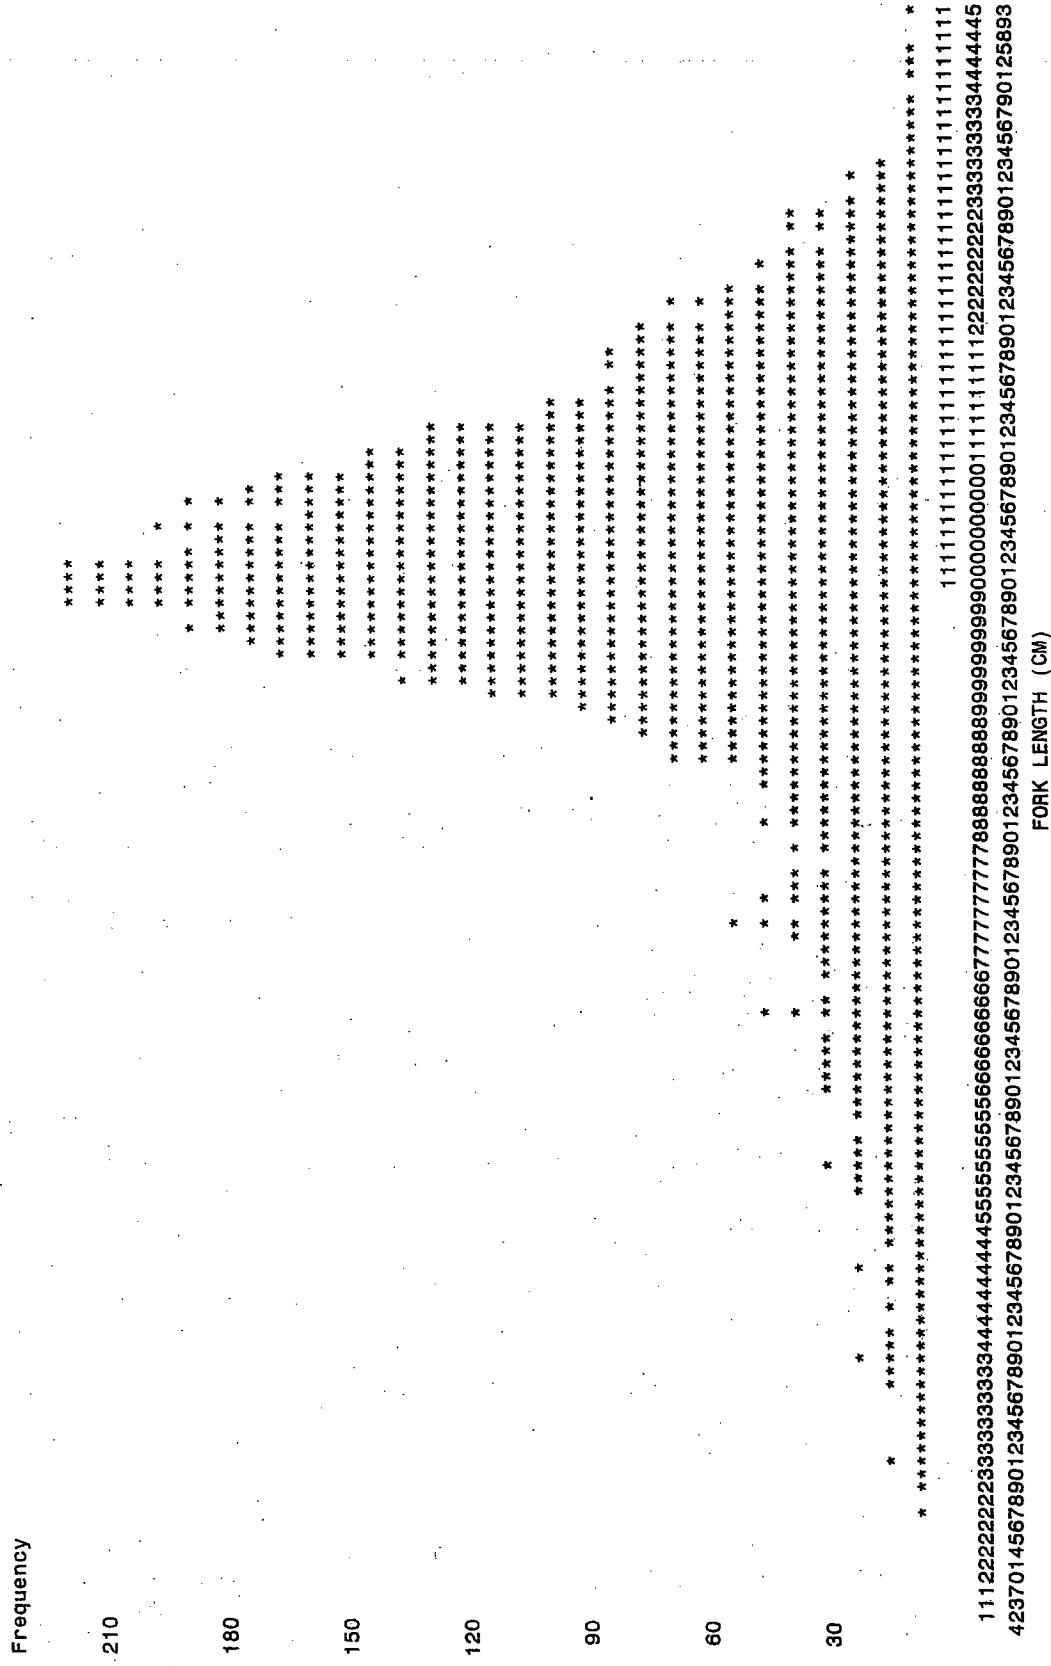

Figure 13b. Atlantic greater amberjack catch sample length distribution for the other commercial other gears for all years combined.

Appendix Table 2FY. Estimated recreational catches of the Atlantic Ocean greater amberjack for the southeastern United States by fishery, state, and fishing year, 1981-1998. Values for 1998 are preliminary.
 Units are number of fish. MRFSS includes Monroe county recreational catches
 (i.e., Florida Keys) in the Florida West Coast catch estimates;
 MRFSS estimates in this table only include catches from Florida East Coast.

Appendix Figure 1FY. Reported commercial landings by fishing year for Atlantic Ocean greater amberjack in the southeastern United States, 1962-1997. Landings from the Florida Keys are included in the Atlantic stock. The 1997 values are preliminary. Units are whole weight (pounds).

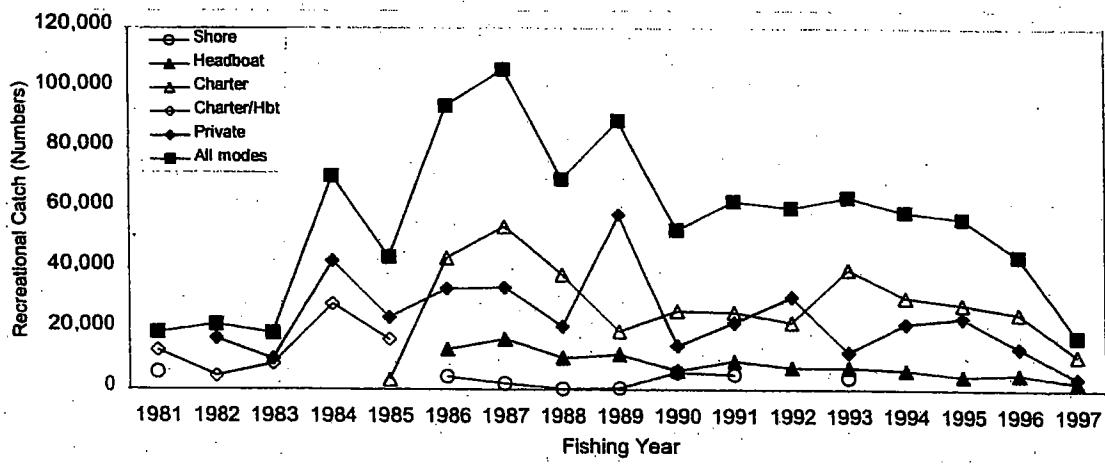

Appendix Figure 2FY. Estimated recreational catch (A+B1) of the Atlantic Ocean greater amberjack for the southeastern United States by source and fishing year, 1981-1997. Values for fishing year 1997 are preliminary. Units are number of fish. MRFSS includes Monroe county recreational catches (i.e., Florida Keys) in the Florida West coast catch estimates; MRFSS estimates in this figure only include catches from Florida East coast.

Appendix Figure 3aFY. Estimated recreational catch (A+B1) of the Atlantic Ocean greater amberjack for the southeastern United States by state and fishing year, 1981-1997. Values for fishing year 1997 are preliminary. Units are number of fish: MRFSS includes Monroe county recreational catches (i.e., Florida Keys) in the Florida West coast catch estimates; MRFSS estimates in this figure only include catches from Florida East coast.

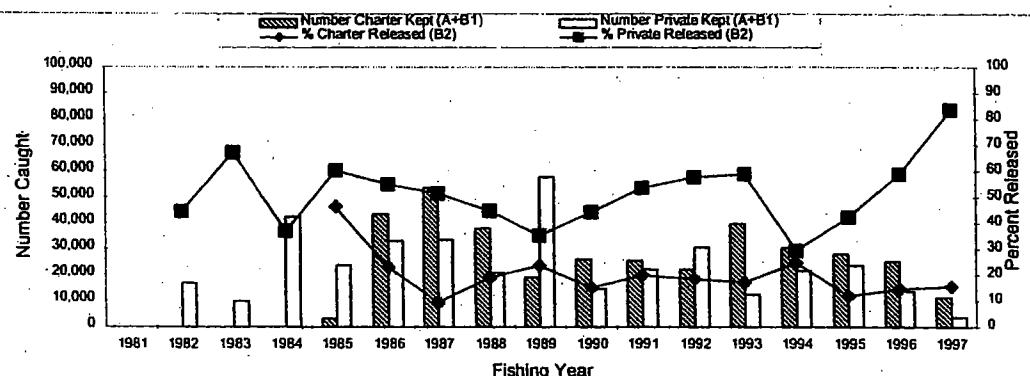

Appendix Figure 3bFY. Estimated recreational catch (A+B) of the Atlantic Ocean greater amberjack for the southeastern United States by fishery and fishing year, 1981-1997. Values for fishing year 1997 are preliminary. Units are number of fish. MRFSS includes Monroe county recreational catches (i.e., Florida Keys) in the Florida West Coast catch estimates; MRFSS estimates in this figure only include catches from Florida East coast.

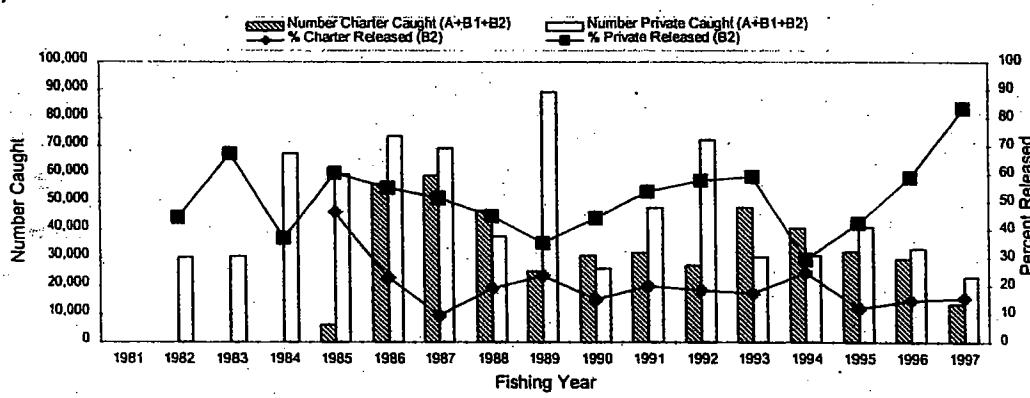

Appendix Figure 4FY. Estimated recreational harvest a) A+ B1 and b)A+ B1 +B2 and disposition (percent released) of Atlantic Ocean greater amberjack by fishing year, based on MRFSS data. Values for fishing year 1997 are preliminary. Percent released equals number released (B2) divided by total caught (A+B1+B2). MRFSS includes Monroe county recreational catches (i.e., Florida Keys) in the Florida West coast catch estimates; MRFSS estimates in this figure only include catches from Florida East coast.

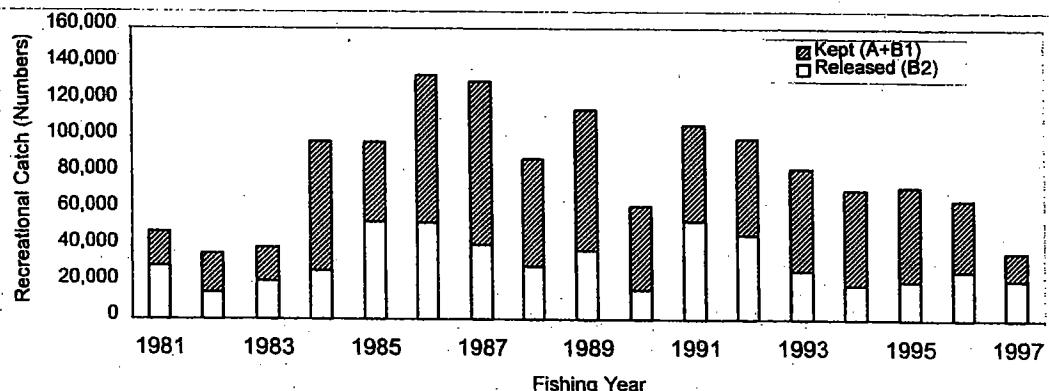

a)

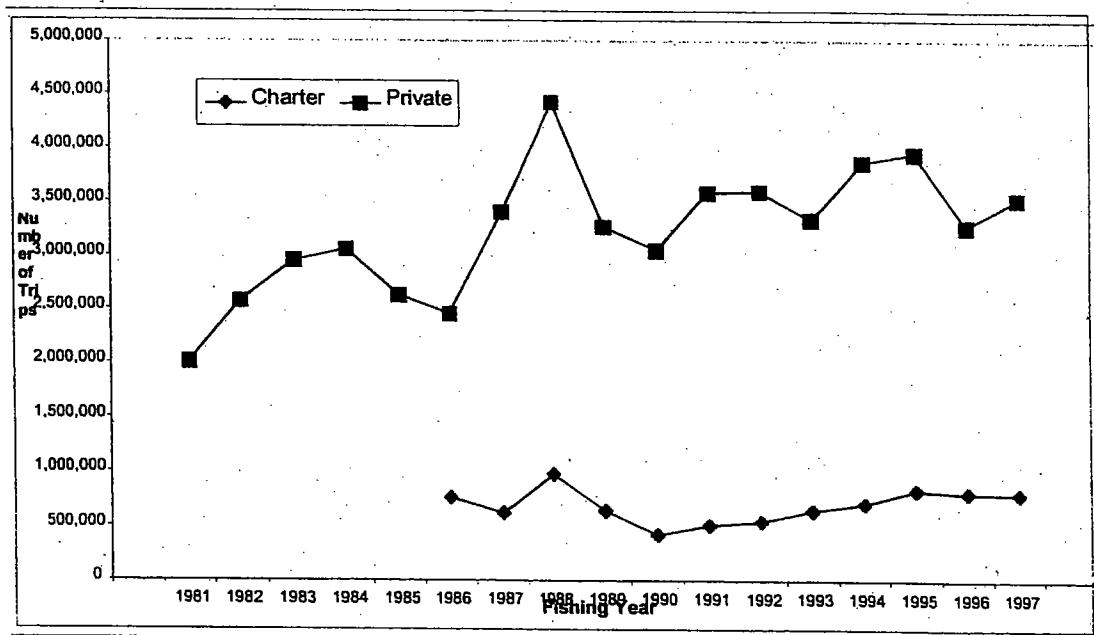

b)

Appendix Figure 5FY. Disposition of greater amberjack caught by recreational fishermen from the Atlantic Ocean by all modes combined and fishing year, 1981-1997 based on MRFSS data. Values from 1997 are preliminary. MRFSS includes Monroe county recreational catches (i.e., Florida Keys) in the Florida West coast catch estimates; MRFSS estimates in this figure only include catches from Florida East coast.

Appendix Figure 6FY. Estimated number of fishing trips by mode and fishing years in the Atlantic Ocean based on the MRFSS survey. The 1997 fishing year values are preliminary.
